THE COOKED WORKS

Cooked FX Environment & Emotes (FREE)

Read me

What is inside

Effects	40 environment and emote effects: ambient, emotes, water, weather
Animations	60 sprite sheets per theme and size (53 seamless loops, 7 one-shot)
Themes	5: Soft Glass, Cozy Chunky, Clean Paper, Flat Night, Pixel (one download per theme, same file names in every theme)
Files per theme	120 PNG sprite sheets (Pixel: 180), *anims.json*, *index.csv*

40 effects (one effect = one distinct design). 2 effects come in a **side** and a **top-down** version and 7 effects in 3 to 4 **colour tones**; counting every version and tone, that is **60 animations** (sprite sheets).

Folder layout

<Theme>/PNG_1x/<sub-set>/<name>.png	vector themes: cells of 128, 192 or 256 px, 24 fps
<Theme>/PNG_2x/<sub-set>/<name>.png	the same sheets at double size
Pixel/PNG_native/<sub-set>/<name>.png	Pixel theme: cells of 32, 48 or 64 px, 12 fps; *Pixel/PNG_1x* = x4, *Pixel/PNG_2x* = x8
<Theme>/anims.json	frames, fps, cell, loop, view, facing, pivot per sheet
<Theme>/index.csv	the same list as a table (opens in any spreadsheet)

File names: *<effect>*, plus *_side* or *_top* when the effect has two versions, plus the tone (*_red*, *_blue*, *_green*, *_purple*, *_yellow*, *_accent* = orange) when it comes in several colours. Example: *env_falling_leaves_side_accent.png*.

Sprite sheets

- Every sheet is a horizontal strip: **frames left to right**, square cells, transparent background.
- Vector themes (Soft Glass, Cozy Chunky, Clean Paper, Flat Night): **24 fps**, PNG_1x cells of 128 px (44 sheets), 192 px (15 sheets), 256 px (1 sheet); PNG_2x is the same sheet at double size. These PNGs use an 8-bit palette with full transparency.
- Pixel theme: **12 fps**, PNG_native cells of 32 px (44 sheets), 48 px (15 sheets), 64 px (1 sheet); PNG_1x = x4 and PNG_2x = x8 (nearest neighbour). Use Point / Nearest filtering and scale only by whole numbers.

How to read anims.json

One entry per sprite sheet. The key is the path below the size folder without *.png*, for example *ambient/env_falling_leaves_side_accent*.

frames	number of frames in the sheet; sheet width = frames x cell, sheet height = cell
fps	playback speed in frames per second
cell	frame size in px in **PNG_1x** (Pixel theme: in **PNG_native**)
cells	frame size per size folder, for example *{PNG_1x: 128, PNG_2x: 256}*

loop	**true**: seamless loop, the last frame flows into the first. **false**: one-shot, play it once and then hide or remove it
view	**side** = for side-view games, **top** = for top-down games, **any** = works in both
faces	**right** for directional effects (rotate or flip them to aim), otherwise null
pivot	the effect's origin as a fraction of the cell, [x, y] from the top-left corner
genre, sub, label	where the effect belongs and its readable name
effect, tone	the design this sheet belongs to and its colour tone (null when there is only one)

Views, pivot, facing

- **Side and top-down**: effects with gravity or ground contact come twice. `_side` is for platformers and other side-view games (things arc, fall and land on the ground line); `_top` is for top-down games (things spread in all directions and stay on the floor). Effects without a suffix work in any view.
- **Pivot**: put the pivot point of the cell on the spot where the effect happens. For side-view sheets it sits on the ground line (the point of impact or the character's feet); for top-down and any-view sheets it is the centre of the cell.
- **Pixel theme, pivot**: side-view pivots fall on a half pixel in **PNG_native** (y = 24.5 in a 32 px cell): round down, or use **PNG_1x** where the pivot is a whole pixel (y = 98 in the 128 px cell).
- **Facing**: directional effects (slashes, shots, dashes, trails) point right, as listed in `faces`. Flip or rotate the sprite for other directions.

How to play a sheet

- **Any engine**: frame *i* is the rectangle x = i x cell, y = 0, width = height = cell. Show frame floor(time x fps); for a loop take it modulo *frames*, for a one-shot stop after the last frame. Draw the cell so that its pivot (pivot x cell) lands on the target position.
- **Unity**: Sprite Mode = Multiple, Sprite Editor > Slice > Grid By Cell Size (cell x cell), pivot = Custom, X = pivot x, Y = 1 - pivot y (Unity measures from the bottom); then drag the frames into the scene to create an animation clip.
- **Godot**: AnimatedSprite2D > SpriteFrames > Add frames from sprite sheet (horizontal = frames, vertical = 1), set the speed to fps.
- **GameMaker**: import the PNG as a strip (Import Strip Image, number of frames = frames) and set the sprite speed to fps.
- **Unreal**: Paper2D > Extract Sprites (Grid, cell x cell), then create a Flipbook at fps frames per second.
